

Question: Discuss an algorithm to traverse a tree, depth first.

Let me start by defining a tree to be a logical collection of entities (nodes), linked together to form a hierarchical structure e.g. an organizational chart or random entries. For the cause of this explanation I will be using the tree example shown below with random char entries.

Ok, so we have a tree structure here.

The depth first algorithm I will be discussing is the “Inorder” Traversal. Well simply put it means we will be using the following rule to traverse the tree:

Left,Read,Right, meaning from the root node of “N” we will move to its left child “A”, assuming “A” has no children, we will then read its value and move to “N” right child which is “.” And apply the same rule to. After treating all child nodes of the root “N”, we return to the parent and read. Thus, we always start with the deepest node on the left in this case.

Let’s, write this out in steps:

InOrder Traversal (InOrder)

1. Go to **left** child node and perform “InOrder” on it.
2. Print out the root value, regardless of it being the actual root.
3. Go to **Right** child node and perform “InOrder” on it.
4. Do this recursively

Now, using the rules and steps above, traversing the tree above will result in:

LORD-MALLAM.N

The Java pseudocode will be:

```
public class Node {

    private Node right;
    private Node left;
    private char nodeValue;

    public Node leftNode() {return left;}
    public Node rightNode() {return right;}
    public char NodeValue() {return nodeValue;}

}

void inOrder (Node root)
{

    if(root == null) return;

    inOrder(root.leftNode());
    root.printNodeValue();
    inOrder(root.rightNode());

}
```

Alright, I guess I am done.

O yes I won't go into discussing its space complexity etc. at this time.

Yours Truly,
Lord-Mallam
